

ABSTRACT OF THE DISCLOSURE

1 A method is provided for replicating DNA, and in particular for replicating
2 large segments of DNA. A primer is combined with a target DNA molecule to be replicated.
3 The primer is designed to be at least partially homologous to a known site on the target
4 DNA, and to create a D-loop when hybridized with that site. A replisome is then assembled
5 at the D-loop, and this replisome creates a copy of the DNA, starting at the primer binding
6 site. By utilizing two species of D-loop primers which bind to remote sites on the DNA
7 flanking a region to be replicated, large sections of DNA can be replicated in a manner
8 comparable to PCR. The replicated DNA can be analyzed to detect variations in the genetic
9 sequence of the target, for linkage mapping and as a source of longer DNA molecules
having a desired sequence.
